

# A Reference Architecture for Applications with Conversational Components

**Saurabh Srivastava**, T.V. Prabhakar

Department of Computer Science & Engineering, IIT Kanpur, India

**10<sup>th</sup> IEEE International Conference on Software Engineering and Service**  
Beijing, China

October 18-20, 2019

# Agenda

- Introduction
  - Applications with Conversational Interfaces
  - Issues with Conversational Interfaces
- Reference Architecture for such applications
  - Major components
  - Common Variation Points
- Examples of Concrete Architectures
  - Using Google's Dialogflow
  - Using IBM's Watson Assistant
- Summary

# Introduction

# Conversational Interfaces

- User-interfaces involving communication through *Natural Language phrases*, say in English or Mandarin are becoming fairly common
- The conversation could be *textual*, i.e. "typed in a textbox", or it could be through *speech*, i.e. "spoken by a synthesised voice"
- The idea is to allow user to express her intentions in a language she is already familiar with
- These mechanisms to interact with a system are called *Conversational Interfaces*
- The colloquial term for these interfaces is *Chatbots*

Please choose one of the following options.

**Check my booking**

Check booking status and get help with flight irregularities

Check my booking

Flight was canceled

Missed my connection

**Baggage**

Get answers to

Check my booking

Alright. Please enter your booking code or ticket number so that I can have a look.

Booking code

Example of a  
*Conversational interface* -  
**Lufthansa Airlines Chatbot**  
Over Facebook Messenger

# Issues with Conversational Interfaces (1/3)

- Core NLP Issues

- Processing Natural Languages is hard, we still haven't reached the 100% success rate !!
- This means models, no matter how accurate, can still make mistakes
- Often, these mistakes cannot be predicted beforehand
- This adds a lot of "uncertainty" when adding these interfaces to systems
- Common issues: converting speech to text and vice versa, understanding sarcasm, word sense disambiguation etc.

# Issues with Conversational Interfaces (2/3)

- Expectations from a *human-like* machine
  - Attempting to be "human-like" may have unexpected consequences
  - The user assumes that the system has answers to questions which may be common knowledge for humans, but not for a machine
  - Example: "How is the weather outside?"
  - Finding out if a question is "answerable" or "not" with the given amount of data is a problem in itself

# Issues with Conversational Interfaces (3/3)

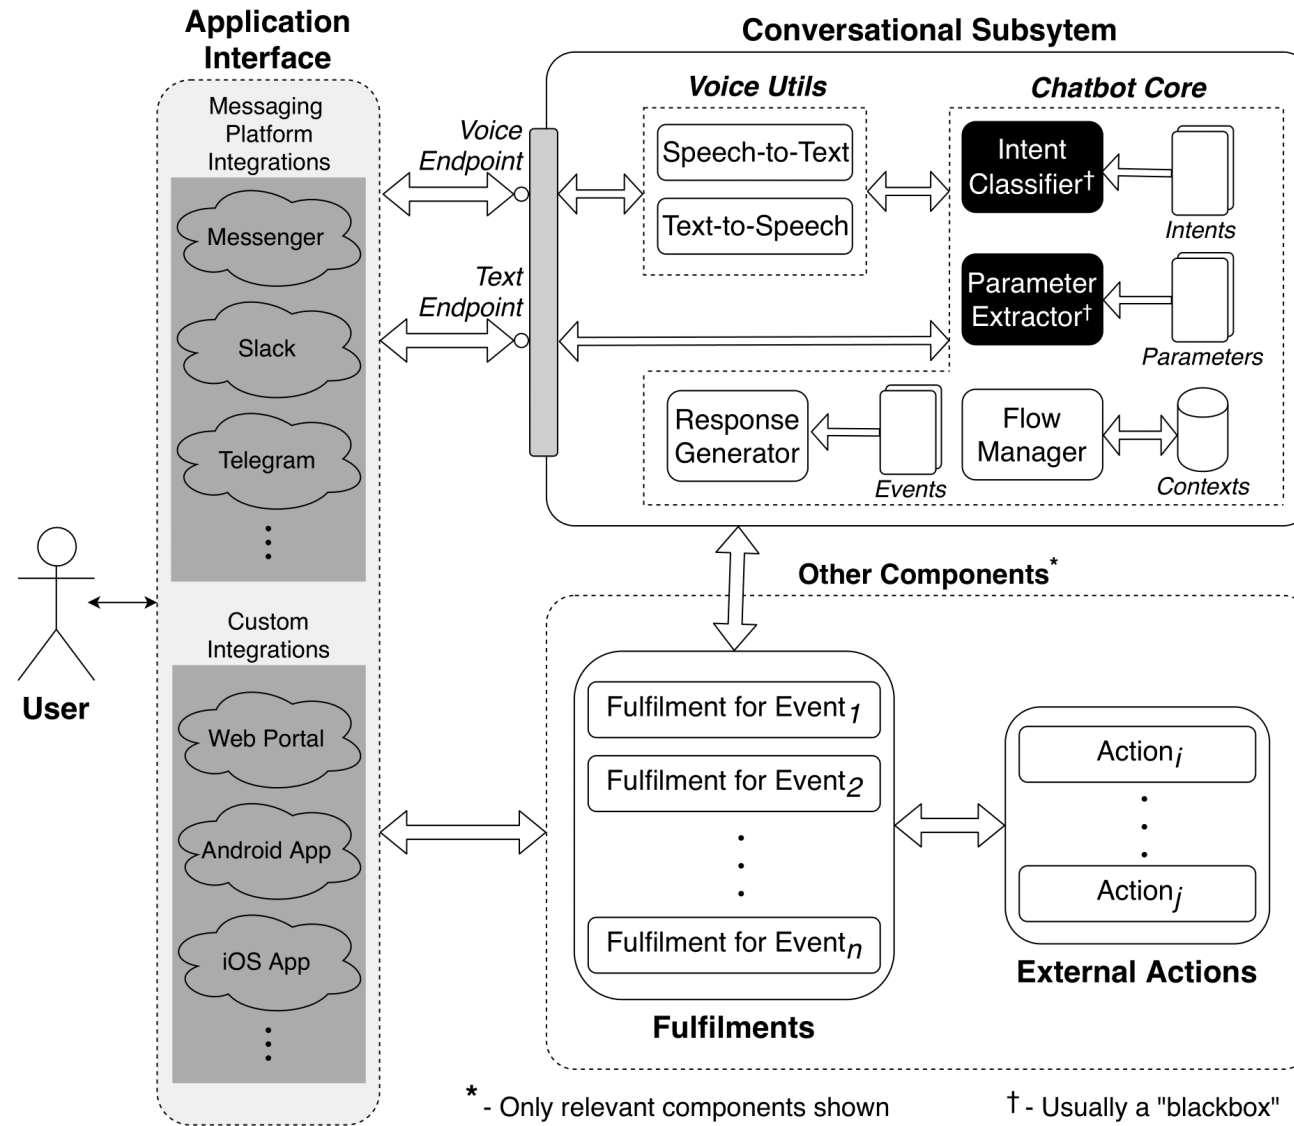

- Operational problems
  - Building these interfaces require building Natural Language models
  - These models require a lot of *example user queries*
  - Even if such large amount of data is actually available, tuning the models to cover all possible types of user queries is not possible
  - Commercial platforms which are often used to build these models (like Google's Dialogflow or IBM's Watson Assistant), usually keep the models "blackboxed"

# Reference Architecture

# Workflow

- A typical workflow for an application with a conversational interface:
  - User enters a query, e.g. "What is the current price for apples"?
  - The chatbot core, contains business logic to find out the "intent" of the user from the supplied query
  - For example, here the intent could be *fruit\_price\_query*
  - The chatbot core also has a mechanism to find out any "parameters" that the query may have, e.g. here the value for *fruit\_name* parameter is *apple*
  - The chatbot then looks for a way to "fulfil" this query – it may involve performing an external "action", such as calling an internal API
  - It may need some context, like user's location, which may have been provided during the conversational "flow" through previous queries
  - Finally, the chatbot prepares and either shows or "speaks" the response back

A Reference Architecture for applications with a conversational interface

# Major Components in the Architecture

- *Intent Classifier*

- This component is responsible for categorising a user query into one of the defined "categories"
- For example, for a store that sells fruits, a user query could be categorised as *fruit\_price\_enquiry* (a query asking for the price of a particular fruit), *store\_address\_enquiry* (a query about the location of the store within the city), *fruit\_availability\_enquiry* (a query about availability of a particular fruit) etc.
- These categories are pre-defined by the chatbot developer, with some examples of each query type

# Major Components in the Architecture

- *Parameter Extractor*

- This component is responsible for finding instances of real-world values in the user query
- For example, for a store that sells fruits, to answer a query about the price of a fruit, it needs the value of the *Fruit* (name of the fruit) parameter, e.g. "apple", "guava" etc.
- Similar to intents, parameters are also pre-defined by the chatbot developer

# Major Components in the Architecture

- *Fulfilments*

- Fulfilments are the code fragments executed for "fulfilling" a user query
- This essentially involves performing any processing tasks in the background, like running SQL queries or calling external APIs

- *Actions*

- Actions are any tasks that can produce an effect in the "outside" world
- For instance, "addition of a reminder to user's calendar" or "sending a mail on behalf of the user"
- Actions are triggered as part of some fulfilments

# Major Components in the Architecture

- *Voice-to-Text*
  - All the models are built to work over "textual" inputs, and provide "textual" outputs
  - If the user query is in speech form, a component is required to transcribe it in text form before supplying it to the model
- *Text-to-Voice*
  - If the user is expecting the response in audio format, a component must produce the same, from the output generated by the model
  - A system voice is required to synthesis this audio clip

# Major Components in the Architecture

- *Response Generator*

- Prepares a response for a given user query
- The response could be an answer to the user's question, or a follow-up question (e.g. to get the value for a parameter, if it was not supplied in the original query)
- The response can either be generated "internally" by the chatbot, by using a pre-defined template, or, it can be directly sent from the respective fulfilment, which in turn, may have been generated "externally"

# Major Components in the Architecture

- *Flow Manager*

- How does these two conversations differ from each other?

Bot: *What can I do for you?*

User: *I want to order fruits*

Bot: *Which fruit?*

User: *What do you have now?*

Bot: *Bananas and Apples.*

Bot: *Which fruit?*

User: *Apples*

Bot: *Ok. Ordering Apples...*

Bot: *What can I do for you?*

User: *I want to order fruits*

Bot: *Which fruit?*

User: *What do you have now?*

Bot: *Sorry, we don't have that!*

Bot: *What can I do for you?*

User: *What fruits do you have?*

Bot: *Bananas and Apples.*

Bot: *What can I do for you?*

User: *I want to order apples*

Bot: *Ok. Ordering Apples...*

- Answer – Flow Management (keeping track of previous context, and changing the response based on that)

# Common points of Variations

- Voice Utils
  - The Voice-to-Text and Text-to-Voice utilities are not required to be a part of the system, if the built chatbot supports only text
  - These tasks can be delegated to an external service or component, and invoked through API calls
- Fulfilments
  - The fulfilment code can be written in multiple technologies
  - The location of the code can also vary – it can be a part of the system itself, or, it could be invoked through API calls
- Flow Management
  - Flow Management is a "nice-to-have" feature
  - For some use cases, it may not even be required

# Concrete Architectures

Built using Commercial Chatbot Development platforms

# Chatbots with Dialogflow and Watson Assistant

\* - Only relevant components shown † - A "blackbox" # - Provided implicitly via WaveNet

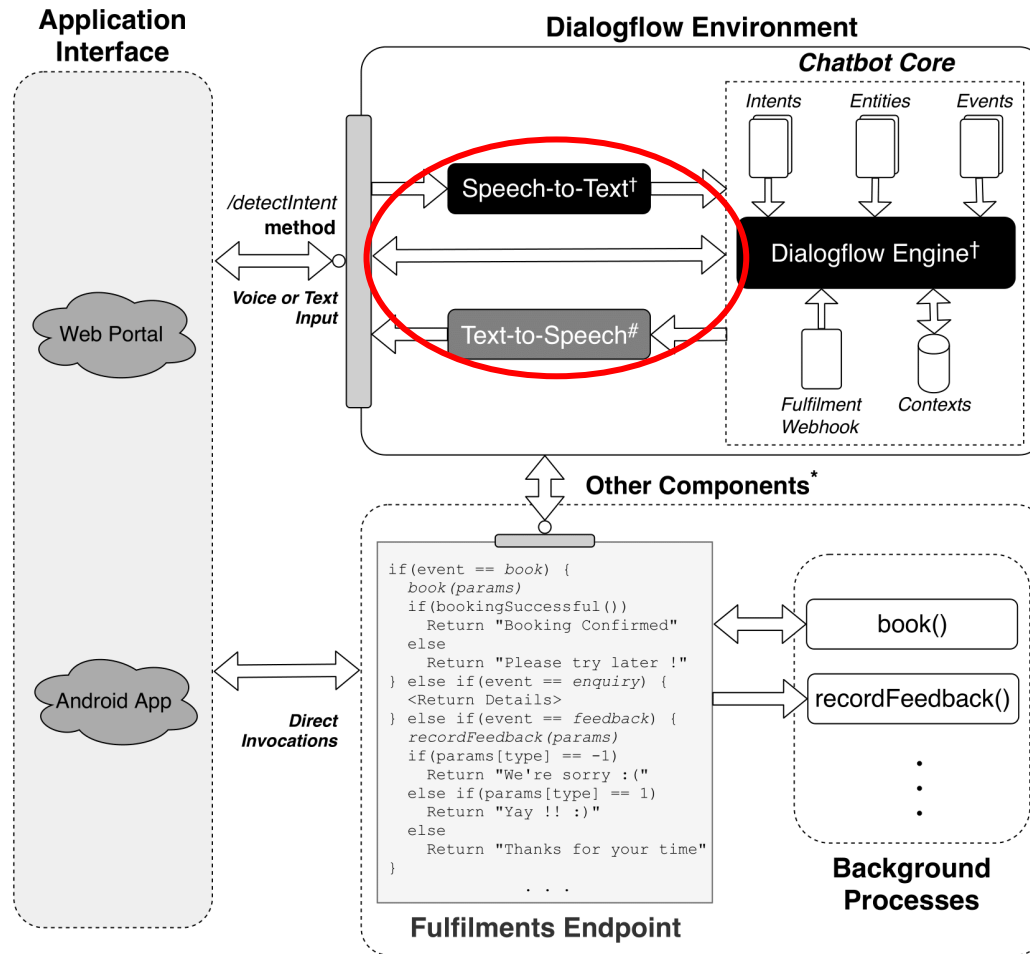

Application built with Dialogflow

\* - Only relevant components shown † - A "blackbox"

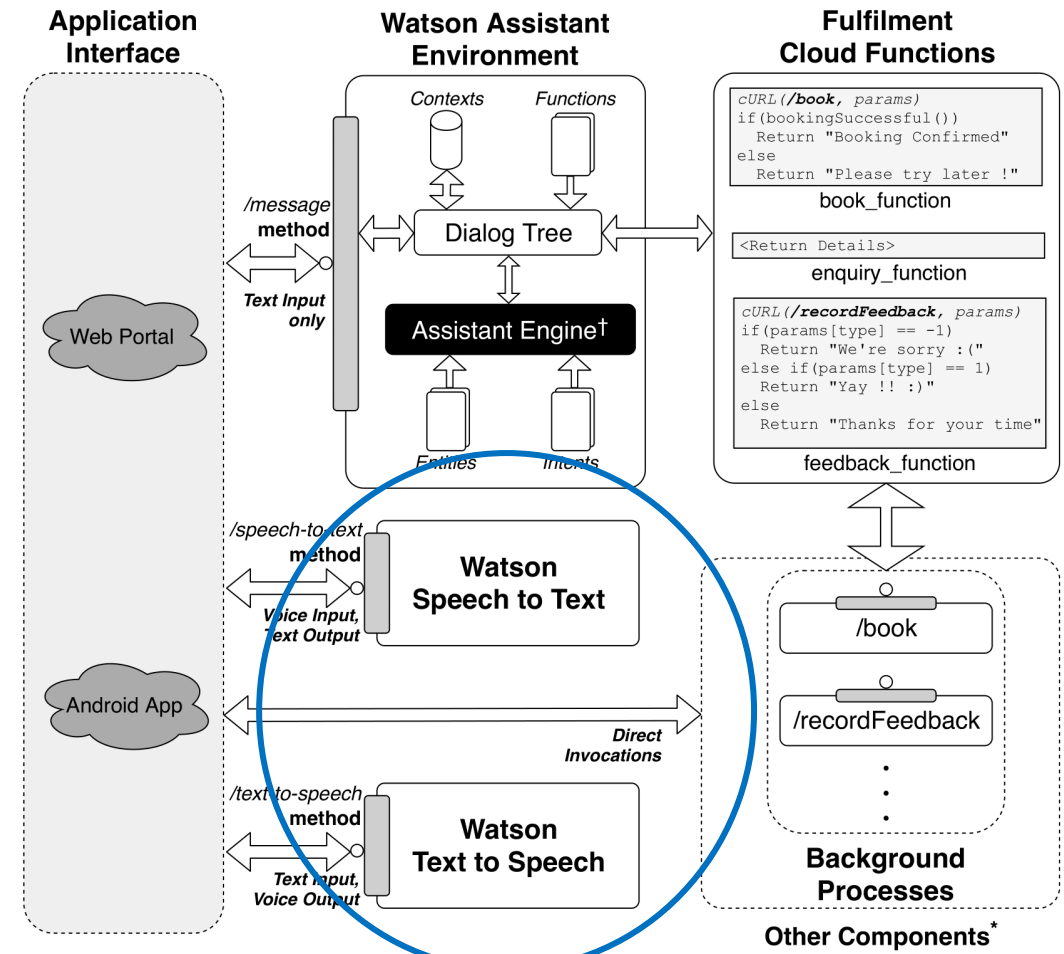

Application built with Watson Assistant

# Chatbots with Dialogflow and Watson Assistant

\* - Only relevant components shown † - A "blackbox" # - Provided implicitly via WaveNet

Application built with Dialogflow

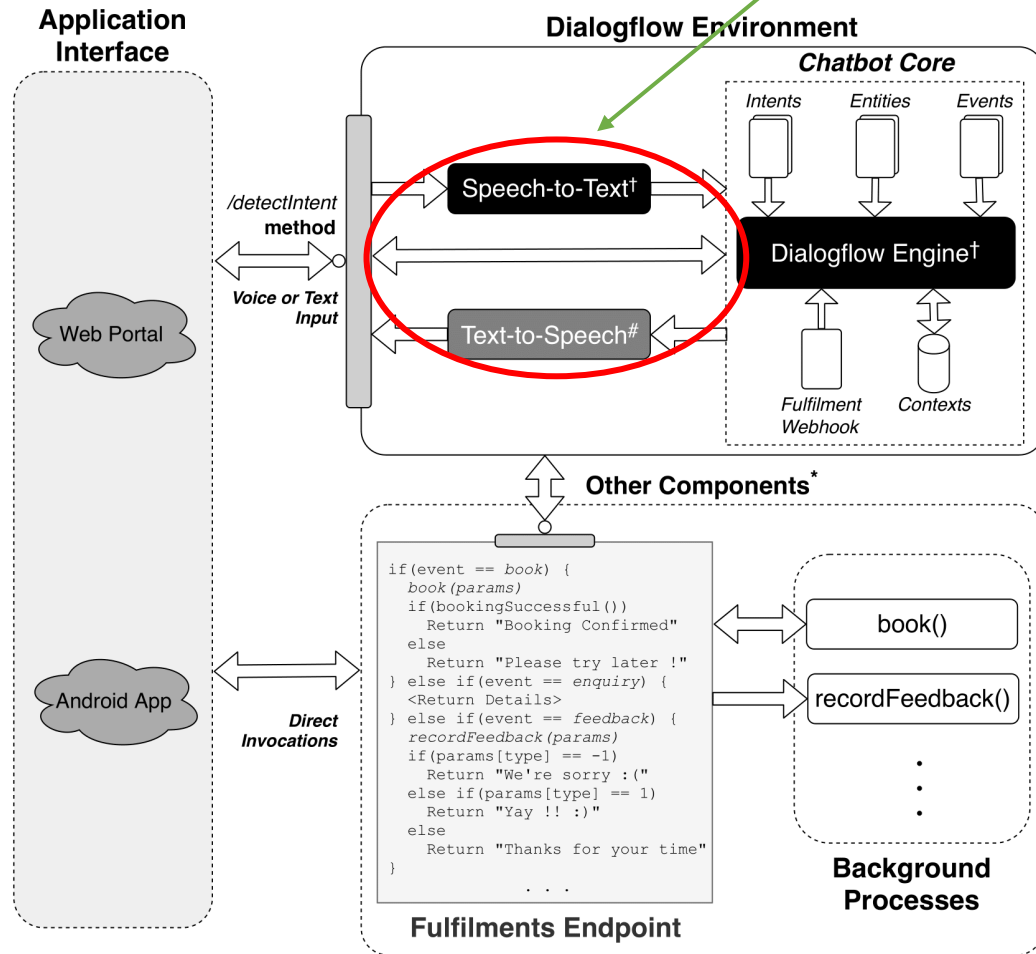

\* - Only relevant components shown † - A "blackbox"

Application built with Watson Assistant

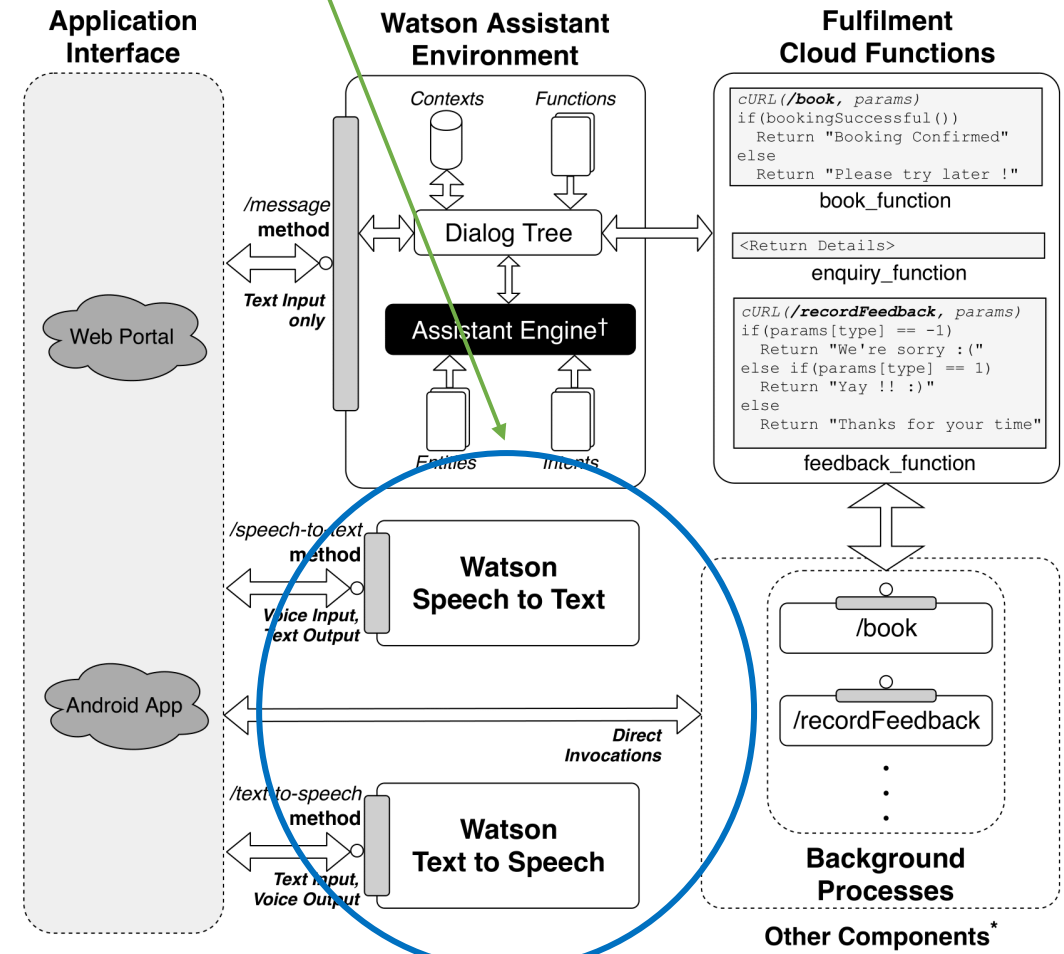

Internal vs External Voice Utils

# Chatbots with Dialogflow and Watson Assistant

\* - Only relevant components shown † - A "blackbox" # - Provided implicitly via WaveNet

Application built with Dialogflow

\* - Only relevant components shown † - A "blackbox"

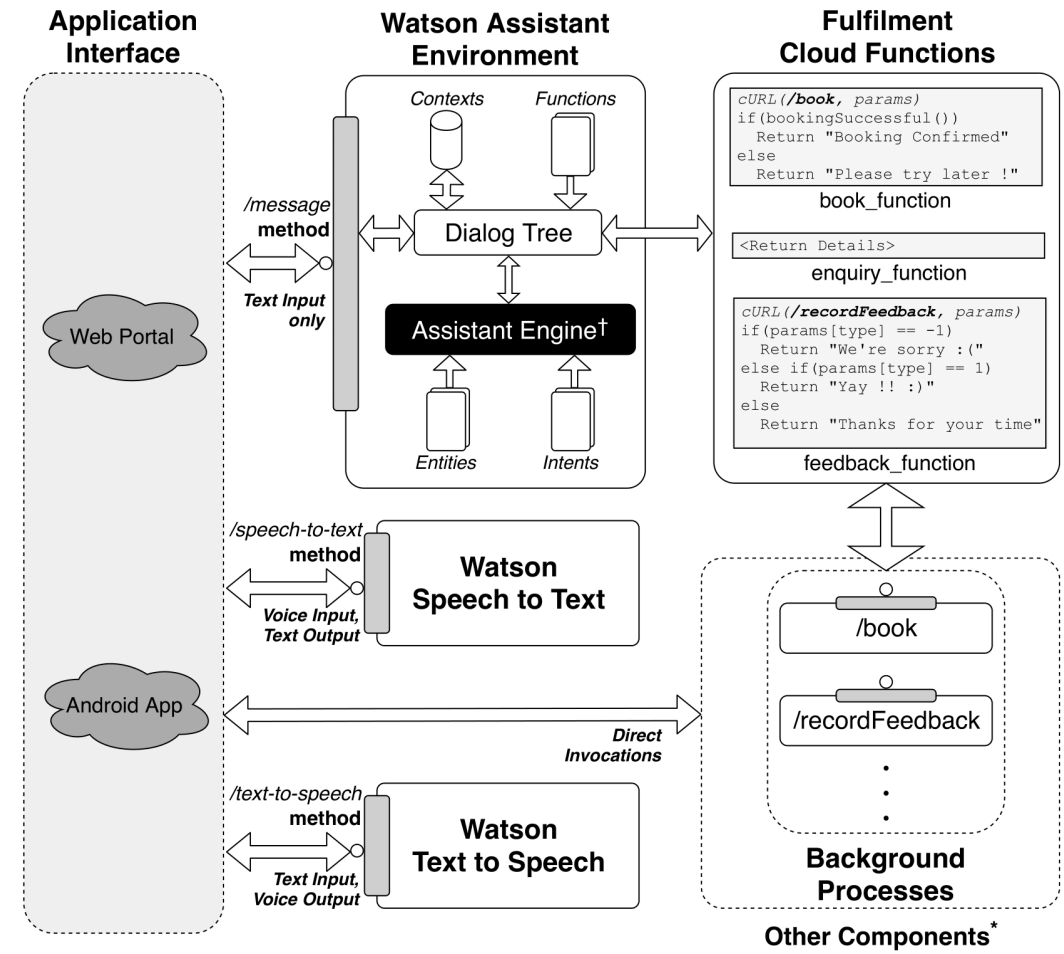

Application built with Watson Assistant

# Chatbots with Dialogflow and Watson Assistant

\* - Only relevant components shown † - A "blackbox" # - Provided implicitly via WaveNet

Application built with Dialogflow

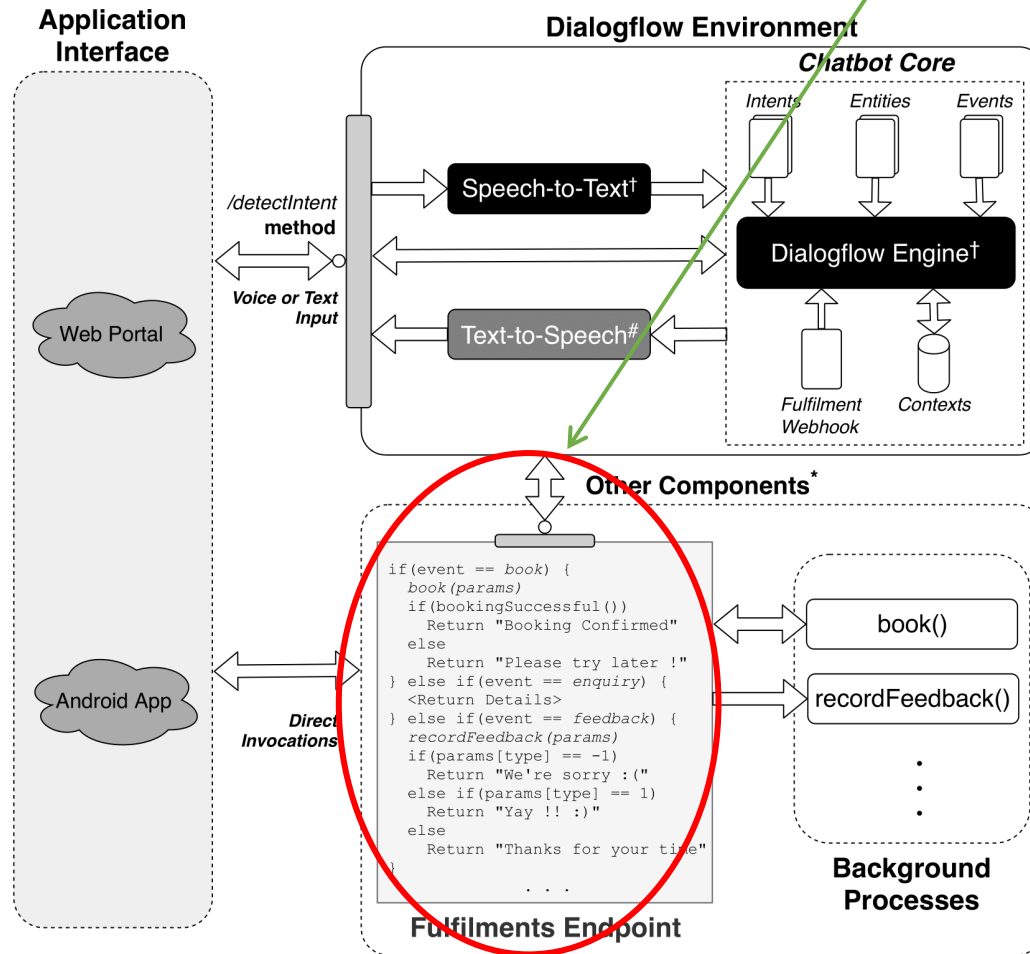

\* - Only relevant components shown † - A "blackbox"

Application built with Watson Assistant

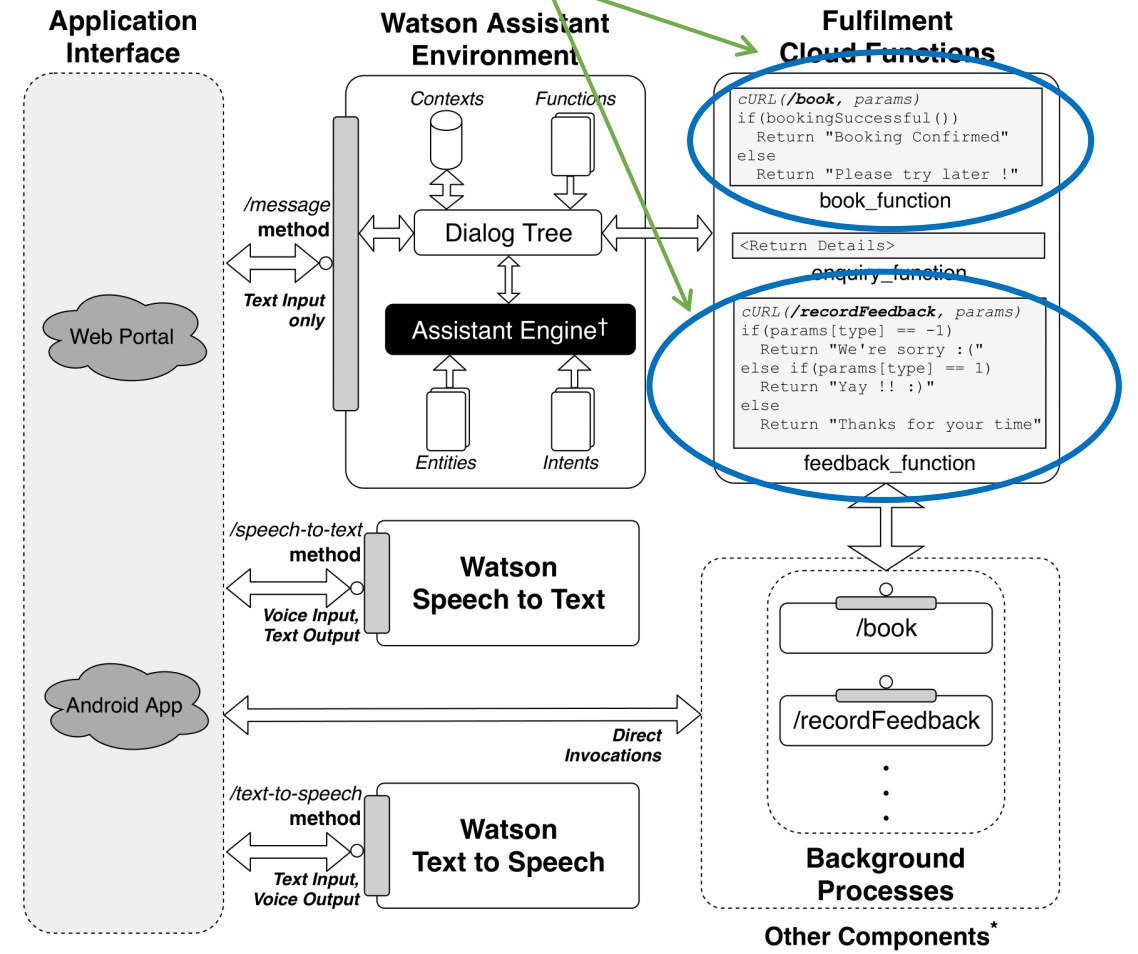

## Single vs Multiple fulfilment hooks

# Chatbots with Dialogflow and Watson Assistant

\* - Only relevant components shown † - A "blackbox" # - Provided implicitly via WaveNet

Application built with Dialogflow

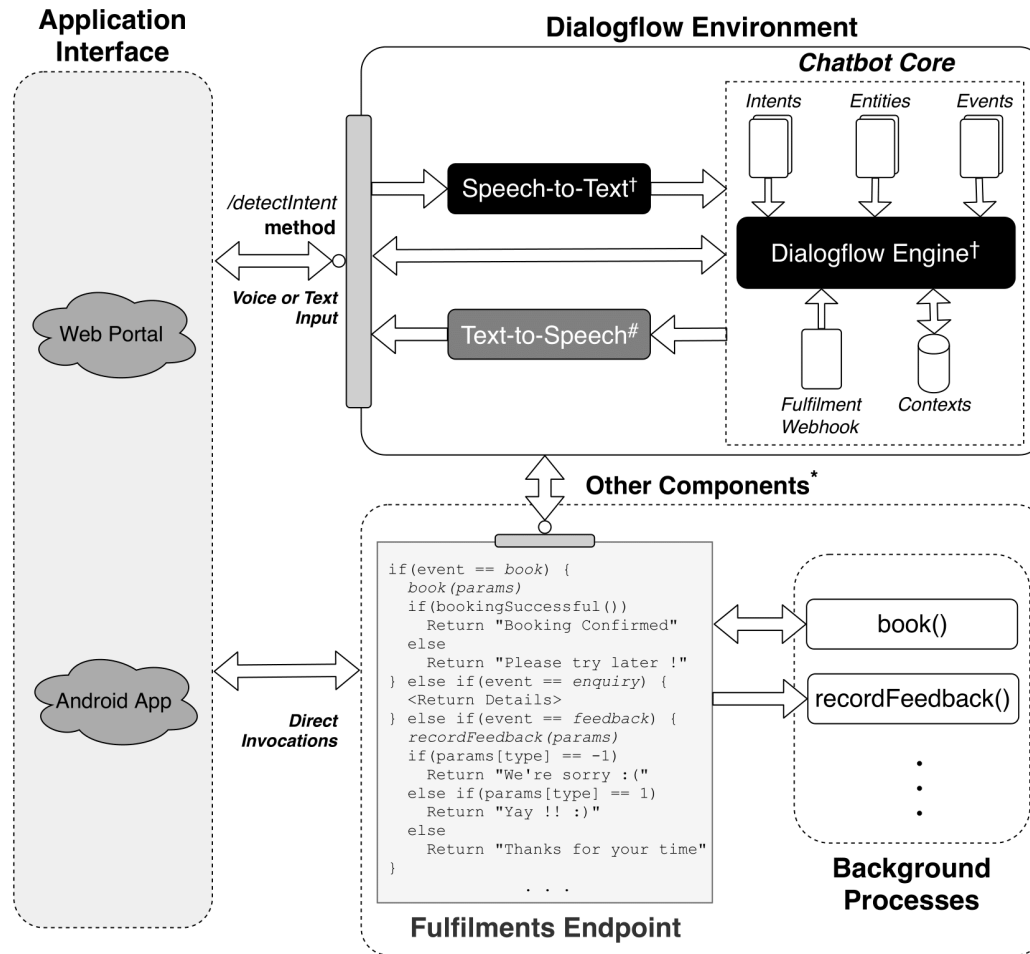

\* - Only relevant components shown † - A "blackbox"

Application built with Watson Assistant

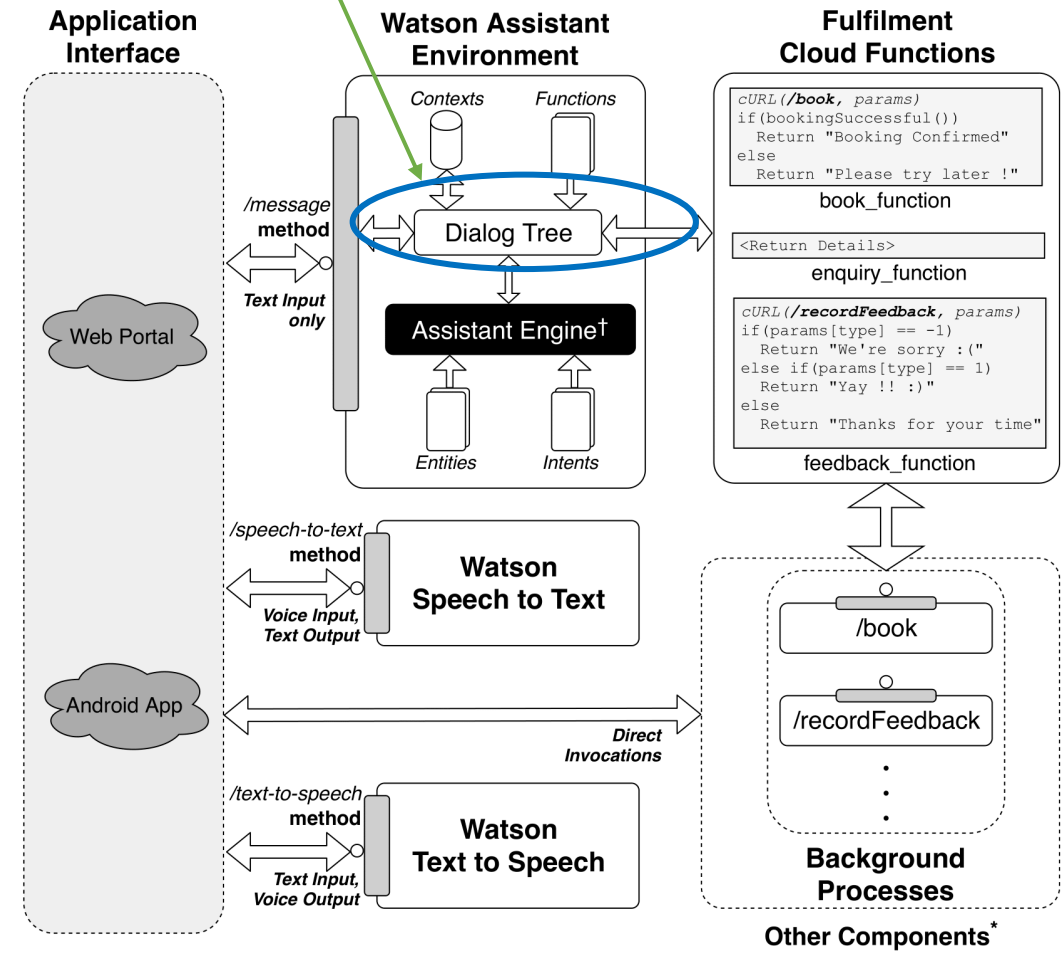

# Chatbots with Dialogflow and Watson Assistant

\* - Only relevant components shown † - A "blackbox" # - Provided implicitly via WaveNet

Application built with Dialogflow

\* - Only relevant components shown † - A "blackbox"

Application built with Watson Assistant

# In a nutshell

- We presented a Reference Architecture for applications with conversational interfaces
- We showed the variation points in the architecture, which can yield different concrete architectures
- We showed concrete architectures of two applications, built using two commercial chatbot-building platforms – Google's Dialogflow and IBM's Watson Assistant
- We showed the variations in the application's architecture, in the above two cases

Thank You !!
